

Scenario:-

A company works with a number of employees; all the works are dependent on the employees. Even if one of the employees resigns, the assigned work will not be finished on time. The delivery of the project to the client will be delayed. To avoid such a situation, the stakeholders want to know which employee may resign next. If they know this, they can arrange an alternative to avoid such emergencies.

As an AI Engineer, you must give a solution to this.

A) We solve this problem by predicting the employee who is going to resign from the company by analysing and predicting the employees data and based on that assign that project to other employees by sharing the project to complete on time.

B) Stage- 1 Machine Learning because the dataset contain text and numbers.

Stage – 2 Supervised Learning because we are going to predict the outcome. And Requirements are very clear and dataset we going to prepare is also having output .

Stage-3 Classification because output column are categorical values like yes/ no.

C) Project name – Employees resign prediction.

D) S.no. Emp_id. Age. Experience. Job satisfaction. Total project. Work like

1.	2221.	35.	4yrs.	Good.	20+.
2.	3372.	27.	1.5 yrs.	Bad.	3.

Balance.	Job Role.	Last Appraisal Rating.	Resigned/Target or output column
----------	-----------	------------------------	----------------------------------

4/5.	Senior.	3.5/5.	No
2/5.	Junior.	1.5/5.	Yes
